

Synergistic Mixtures of UV-Absorbers in Polyolefins

The present invention relates to novel polyolefin compositions which contain mixtures of different UV absorbers.

The effects of atmospheric oxygen, moisture and, in particular, UV light result in degradation of the polymer material. This manifests itself, for example, in the loss of mechanical strength, changes in shade and finally total breakdown of the polymer article. As is known, it is possible to retard such degradation processes in polyolefins by the use of suitable stabilizers, and there are numerous prior art documents in this field.

In the coatings field, EP-A-0453 396 discloses that mixtures of hydroxyphenyl-benzotriazole with hydroxybenzophenone or with hydroxyphenyl-s-triazine UV-absorbers lead to synergistic mixtures which prevent the coatings life time unexpectedly long from degradation.

Although there are prior art documents, such as FR 2619 814, which generically disclose the combined use of oxalamide UV absorbers, particularly in coatings, with benzophenone or benzotriazole UV absorbers, there is however no suggestion in the prior art for the instant combinations in polyolefins.

It has now been found that certain combinations of UV absorbers of different chemical structures are capable of substantially preventing the degradation of polyolefins.

The combinations of the present invention provide an unexpected synergistic stabilization effect for polyolefin articles. The effect is not predictable from the absorption spectra and has not been observed with other UV absorber combinations in polyolefins.

One subject of the present invention is a polyolefin composition which comprises as UV absorber a mixture of

- a) at least one hydroxybenzophenone and at least one 2-hydroxyphenylbenzotriazole with the proviso that the polyolefin is a high density polyethylene of the "Phillips" type or a polyethylene of the metallocene type;
- b) at least one hydroxybenzophenone and at least one 2-hydroxyphenyltriazine, with the proviso that if the polyolefin is polypropylene, no polyvinylpyridin is present

- c) at least one hydroxybenzophenone and at least one oxanilide;
- d) at least one 2-hydroxyphenylbenzotriazole and at least one oxanilide;
- e) at least one 2-hydroxyphenyltriazine and at least one oxanilide;
- f) at least one hydroxybenzophenone, at least one 2-hydroxyphenylbenzotriazole and at least one oxanilide;
- g) at least one hydroxybenzophenone, at least one oxanilide and at least one 2-hydroxyphenyltriazine; or
- h) at least one 2-hydroxyphenylbenzotriazole, at least one oxanilide and at least one 2-hydroxyphenyltriazine.

Suitable polyolefins are mentioned below.

1. Polymers of monoolefins and diolefins, for example polypropylene, polyisobutylene, polybut-1-ene, poly-4-methylpent-1-ene, polyisoprene or polybutadiene, as well as polymers of cycloolefins, for instance of cyclopentene or norbornene, polyethylene (which optionally can be crosslinked), for example high density polyethylene (HDPE), high density and high molecular weight polyethylene (HDPE-HMW), high density and ultrahigh molecular weight polyethylene (HDPE-UHMW), medium density polyethylene (MDPE), low density polyethylene (LDPE), linear low density polyethylene (LLDPE), (VLDPE) and (ULDPE), metallocene polyethylen (m-PE) in particular m-LLDPE and metallocene polypropylene (m-PP).

Polyolefins, i.e. the polymers of monoolefins exemplified in the preceding paragraph, preferably polyethylene and polypropylene, can be prepared by different, and especially by the following, methods:

- a) radical polymerisation (normally under high pressure and at elevated temperature).
- b) catalytic polymerisation using a catalyst that normally contains one or more than one metal of groups IVb, Vb, VIb or VIII of the Periodic Table. These metals usually have one or more than one ligand, typically oxides, halides, alcoholates, esters, ethers, amines, alkyls, alkenyls and/or aryls that may be either  $\pi$ - or  $\sigma$ -coordinated. These metal complexes may be in the free form or fixed on substrates, typically on activated magnesium chloride, titanium(III) chloride, alumina or silicon oxide. These catalysts may be soluble or insoluble in the polymerisation medium. The catalysts can be used by themselves in the polymerisation or further activators may be used,

typically metal alkyls, metal hydrides, metal alkyl halides, metal alkyl oxides or metal alkyloxanes, said metals being elements of groups Ia, IIa and/or IIIa of the Periodic Table. The activators may be modified conveniently with further ester, ether, amine or silyl ether groups. These catalyst systems are usually termed Phillips, Standard Oil Indiana, Ziegler (-Natta), TNZ (DuPont), metallocene or single site catalysts (SSC).

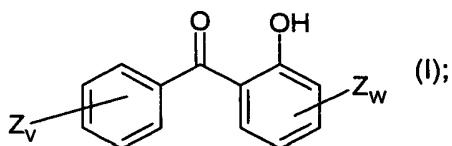

2. Mixtures of the polymers mentioned under 1), for example mixtures of polypropylene with polyisobutylene, polypropylene with polyethylene (for example PP/HDPE, PP/LDPE) and mixtures of different types of polyethylene (for example LDPE/HDPE), metallocene types with conventional types (for example m-PE/PE-LLD, m-PE/PE-LD, m-PP/conventional PP).

In the compounds of the formula (IIa) R<sub>1</sub> can be hydrogen or alkyl having 1 to 24 carbon atoms, such as methyl, ethyl, propyl, butyl, hexyl, octyl, nonyl, dodecyl, tetradecyl, hexadecyl, octadecyl, nonadecyl and eicosyl and also corresponding branched isomers. Furthermore, in addition to phenylalkyl having 1 to 4 carbon atoms in the alkyl moiety, for example benzyl, R<sub>1</sub> can also be cycloalkyl having 5 to 8 carbon atoms, for example

cyclopentyl, cyclohexyl and cyclooctyl, or a radical of the formula  $\begin{array}{c} R_4 \\ | \\ -C- \\ | \\ R_5 \end{array} C_n H_{2n+1-m} - M_m$  in

M is

a radical of the formula  $-\text{COOR}_6$  in which  $\text{R}_6$  is not only hydrogen but also alkyl having 1 to 12 carbon atoms or alkoxyalkyl having 1 to 20 carbon atoms in each of the alkyl and alkoxy moieties. Suitable alkyl radicals  $\text{R}_6$  are those enumerated for  $\text{R}_1$ . Examples of suitable alkoxyalkyl groups are  $-\text{C}_2\text{H}_4\text{OC}_2\text{H}_5$ ,  $-\text{C}_2\text{H}_4\text{OC}_8\text{H}_{17}$  and  $-\text{C}_4\text{H}_8\text{OC}_4\text{H}_9$ . As phenylalkyl having 1 to 4 carbon atoms,  $\text{R}_6$  is, for example, benzyl, cumyl,  $\alpha$ -methylbenzyl or phenylbutyl.

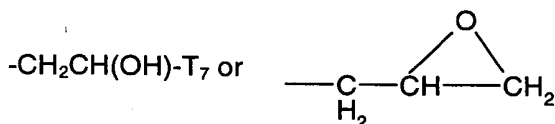

In addition to hydrogen and halogen, for example chlorine and bromine,  $\text{R}_2$  can also be alkyl having 1 to 18 carbon atoms. Examples of such alkyl radicals are indicated in the definitions of  $\text{R}_1$ .  $\text{R}_2$  can also be phenylalkyl having 1 to 4 carbon atoms in the alkyl moiety, for example benzyl,  $\alpha$ -methylbenzyl and cumyl.

Halogen as a substituent means in all cases fluorine, chlorine, bromine or iodine, preferably chlorine or bromine and more preferably chlorine.

At least one of the radicals  $\text{R}_1$  and  $\text{R}_2$  must be other than hydrogen.

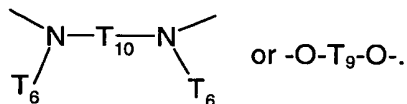

In addition to hydrogen or chlorine,  $\text{R}_3$  is also alkyl or alkoxy having in each case 1 to 4 carbon atoms, for example methyl, butyl, methoxy and ethoxy, and also  $-\text{COOR}_6$ .

In the compounds of the formula (IIb)  $\text{T}$  is hydrogen or alkyl having 1 to 6 carbon atoms, such as methyl and butyl,  $\text{T}_1$  is not only hydrogen or chlorine, but also alkyl or alkoxy having in each case 1 to 4 carbon atoms, for example methyl, methoxy and butoxy, and, if  $n$  is 1,  $\text{T}_2$  is chlorine or a radical of the formula  $-\text{OT}_3$  or  $-\text{NT}_4\text{T}_5$ .  $\text{T}_3$  is here hydrogen or alkyl having 1 to 18 carbon atoms (cf. the definition of  $\text{R}_1$ ). These alkyl radicals can be substituted by 1 to 3 hydroxyl groups or by a radical  $-\text{OCOT}_6$ . Furthermore,  $\text{T}_3$  can be alkyl having 3 to 18 carbon atoms (cf. the definition of  $\text{R}_1$ ) which is interrupted once or several times by  $-\text{O}-$  or  $-\text{NT}_6-$  and is unsubstituted or substituted by hydroxyl or  $-\text{OCOT}_6$ . Examples of  $\text{T}_3$  as cycloalkyl are cyclopentyl, cyclohexyl or cyclooctyl.  $\text{T}_3$  can also be alkenyl having 2 to 18 carbon atoms. Suitable alkenyl radicals are derived from the alkyl radicals enumerated in the definitions of  $\text{R}_1$ . These alkenyl radicals can be substituted by hydroxyl. Examples of  $\text{T}_3$  as phenylalkyl are benzyl, phenylethyl, cumyl,  $\alpha$ -methylbenzyl or benzyl.  $\text{T}_3$  can also be a radical of the formula

Like T<sub>3</sub>, T<sub>4</sub> and T<sub>5</sub> can, independently of one another, be not only hydrogen but also alkyl having 1 to 18 carbon atoms or alkyl which has 3 to 18 carbon atoms and is interrupted once or several times by -O- or -NT<sub>6</sub>-. T<sub>4</sub> and T<sub>5</sub> can also be cycloalkyl having 5 to 12 carbon atoms, for example cyclopentyl, cyclohexyl and cyclooctyl. Examples of T<sub>4</sub> and T<sub>5</sub> as alkenyl groups can be found in the illustrations of T<sub>3</sub>. Examples of T<sub>4</sub> and T<sub>5</sub> as phenylalkyl having 1 to 4 carbon atoms in the alkyl moiety are benzyl or phenylbutyl. Finally, these substituents can also be hydroxyalkyl having 1 to 3 carbon atoms.

If n is 2, T<sub>2</sub> is a divalent radical of the formula

In addition to hydrogen, T<sub>6</sub> (see above also) is alkyl, cycloalkyl, alkenyl, aryl or phenylalkyl; examples of such radicals have already been given above.

In addition to hydrogen and the phenylalkyl radicals and long-chain alkyl radicals mentioned above, T<sub>7</sub> can be phenyl or hydroxyphenyl and also -CH<sub>2</sub>OT<sub>8</sub> in which T<sub>8</sub> can be one of the alkyl, alkenyl, cycloalkyl, aryl or phenylalkyl radicals enumerated.

The divalent radical T<sub>9</sub> can be alkylene having 2 to 8 carbon atoms, and such radicals can also be branched. This also applies to the alkenylene and alkynylene radicals T<sub>9</sub>. As well as cyclohexylene, T<sub>9</sub> can also be a radical of the formula -CH<sub>2</sub>CH(OH)CH<sub>2</sub>OT<sub>11</sub>OCH<sub>2</sub>CH(OH)CH<sub>2</sub>- or -CH<sub>2</sub>-C(CH<sub>2</sub>OH)<sub>2</sub>-CH<sub>2</sub>-.

T<sub>10</sub> is a divalent radical and, in addition to cyclohexylene, is also alkylene which has 2 to 20 carbon atoms and which can be interrupted once or several times by -O-. Suitable alkylene radicals are derived from the alkyl radicals mentioned in the definitions of R<sub>1</sub>.

T<sub>11</sub> is also an alkylene radical. It contains 2 to 8 carbon atoms or, if it is interrupted once or several times by -O-, 4 to 10 carbon atoms. T<sub>11</sub> is also 1,3-cyclohexylene, 1,4-cyclohexylene,

1,3-phenylene or 1,4-phenylene.

Together with the two nitrogen atoms, T<sub>6</sub> and T<sub>10</sub> can also be a piperazine ring.

Examples of alkyl, alkoxy, phenylalkyl, alkylene, alkenylene, alkoxyalkyl and cycloalkyl radicals and also alkylthio, oxaalkylene or azoalkylene radicals in the compounds of the formulae (2), (3) and (4) can be deduced from the above statements.

The UV absorbers of the formulae (I), (IIa), (IIb), (IIc), (III) and (IV) are known per se and are described, together with their preparation, in, for example, EP-A-323 408, EP-A-57 160, US 5 736 597 (EP-A-434 608), US-A 4 619 956, DE-A 31 35 810 and GB-A 1 336 391.

Preferred meanings of substituents and individual compounds can be deduced from the documents mentioned.

The compounds can be incorporated into polyolefins by customary methods which are known per se. The preparation may be carried out in a manner known *per se* by mixing the said components and, if desired, further additives with the polymer using devices known *per se*, such as calenders, mixers, kneaders, extruders and the like. The additives may be added individually or in admixture with one another. It is also possible to use so-called master batches.

In certain cases it can be advantageous to use even a mixture of compounds of all 4 classes of UV-absorbers (hydroxybenzophenone, 2-hydroxyphenyltriazine, oxanilide and 2-hydroxyphenylbenzotriazole).

The polyolefin composition obtainable according to the present invention can be made into the desired form in known manner. Such processes include, for example, grinding, calendering, extruding, injection-moulding, sintering, compression/sintering or spinning, also extrusion blow-moulding.

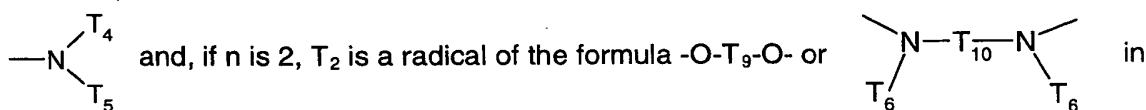

The amounts of UV absorber to be selected can depend on the nature of the polyolefin composition and the requirements for its stability. The individual UV absorber components can be added on their own or as a mixture to the appropriate polyolefin compositions. The customary other additives, such as processing stabilizers, antioxidants and other light

stabilisers, can also be added to the polyolefin compositions, without thereby impairing the protective action of the UV absorber mixtures employed in accordance with the invention.

#### **Example 1: Light stabilization of PP homopolymer films**

100 parts of unstabilized polypropylene powder (melt flow index 3.2 g/10 minutes, 230°C / 2160 g) are homogenized at 200°C for 10 minutes in a Brabender plastograph with 0.05 parts of pentaerythrityl-tetrakis-3-(3,5-ditert.butyl-4-hydroxyphenyl)-propionate, 0.05 parts of tris-(2,4-di-tert.butylphenyl)-phosphite, 0.1 parts of Ca stearate and the amount of light stabilizer indicated in table 1. The material thus obtained is compression molded in a laboratory press between two aluminum foils for 6 minutes at 260°C to a 0.5 mm thick film which is cooled immediately to room temperature in a water-cooled press. Samples of 60 x 25 mm are cut out of these 0.5 mm films and exposed in a WEATHER-OMETER Ci 65 (black panel temperature 63±2°C, without water-spraying)

The exposure time corresponding to formation of a carbonyl absorbance of 0.1 is a measure for the stabilizing efficiency of the light stabilizer. The values obtained are summarized in the following table (Table 1).

#### Example 4: Light stabilization of PE-LD films

100 parts of unstabilized low density polyethylene powder (density: 0.918, melt flow index 0.3 g/10 minutes at 190°C / 2160 g) are homogenized at 180°C for 10 minutes in a Brabender plastograph with 0.02 parts of octadecyl 3-(3,5-di-tert.-butyl-4-hydroxyphenyl)-propionate, 0.08 parts of tris-( 2,4-di-tert.butylphenyl )-phosphite and the amount of light stabilizer indicated in the table. The material thus obtained is compression molded in a laboratory press between two aluminum foils for 6 minutes at 170°C to a 0.5 mm thick film which is quenched immediately in cold water. Samples of 60 x 25 mm are cut out of these 0.5 mm films and exposed in a WEATHER-OMETER Ci 65 (black panel temperature 63±2°C, without water-spraying).

Periodically, these samples are removed from the exposure apparatus and their carbonyl content is measured with an infrared spectrophotometer.

The exposure time corresponding to formation of a carbonyl absorbance of 0.1 is a measure for the stabilizing efficiency of the light stabilizer. The values obtained are summarized in the following table.

#### Example 5: Light stabilization of PE-LLD films

100 parts of unstabilized linear low density polyethylene (PE-LLD) powder (density: 0.920, melt flow index 1.0 g/10 minutes at 190°C/2160 g) are homogenized at 180°C for 10 minutes in a Brabender plastograph with 0.02 parts octadecyl 3-(3,5-di-tert.-butyl-4-hydroxyphenyl)-propionate, 0.08 parts tris-( 2,4-di-tert.butylphenyl )-phosphite, 0.1 parts Ca stearate and the amounts light stabilizers indicated in table 5. Similarly 100 parts of unstabilized metallocene polyethylene powder (density: 0.905, 10% butene comonomer, melt flow index 1.4 g/10 minutes at 190°C/2160 g) are homogenized at 180°C for 10 minutes in a Brabender plastograph with 0.02 parts octadecyl 3-(3,5-di-tert.-butyl-4-hydroxyphenyl)-propionate, 0.08 parts tris-( 2,4-di-tert.butylphenyl )-phosphite, 0.1 parts Ca stearate and the amounts light stabilizers indicated in table 5a (see also example 6). The material thus obtained is compression molded in a laboratory press between two aluminum foils for 6 minutes at 170°C to a 0.5-mm thick film, which is quenched immediately in cold water. Samples of 60 x
